## BOTANICAL NOTES AT MALLACOOTA

By C. S. Hart, m.a., h.c.e.

These notes are fased mainly on observations made last New Year, when I was invited to accompany a camping party. I had also specimens coilecred in previous years, at the same season, by Miss E. K. Turner, who slowed me several itheresting localities. Some of these plants have already been exhibited and reoorded in the Now wralist, Atthough late in the season for many kinds of flowers, a large number of species was identified, including several which occur in Victaria, in the eastern parts only.

Early observers offen reached Maslacoota by diffeult roads; by boat from Genoa; but the settlement is now easily accessible by a gond rad. Several different types of vegetation can be reached within half an hour's walk from the township, and the very attractive steeper couritry to the north-east may be conveniently reached by hoat. The climate is that characteristic of the far east of Gipps-land-good rainfall, and much of it in summer, which makes for fuxuriance in vegetation, especially in such favonier spots as the lower parts of the valleys.

At the towiship you find yourself in a grassland witl scattered trees, no doubt formerly wefl covered, Angophorit intarmedio is the chief tree at this part, with some fairly tail Black Wattles and the Bracelet Honey Myrtle (Mulateuca armiltaris), both as trees and as dense bushes. Along the actual margin of the lake, with a low cliff or short slope, are the Coast Banksia and some typical eastern plants-the large Mock-Olive (Notelara Iongifolia) and the Blue Olive-lierty (Elacocurpus cyamaus), with fringed flowers, and the well-known Pittosporum wadulduyn. The Mock-Olive and Olive-berry belong to quite different familics. In the forest close behind, the Eucalypts are not ahways easily identifed, flowers and fruits being mostly out of reach. Bloorhoods (E. gamminifura) formerly called E. coryndora, are plentiful, and the fallen truits establish their identity. The very distinctive young growth calls attention to the Silvertop (E. sieberiuna) .

In the undergrowth the Shrubby Trachymene (T. Bitiardieri) is conspicuous in summer. This plant is very variable in lear shapeThe Wart-fower (Tyiophord barbata) twines anong the low vegetation. This is an asclepiad cliniber, but docs not show the milky juice usual in the fanily or at Jeast not readily. The Dusky Coral Pea (Konntedya rubriculde) occurs at places. On the ground near the settlement are large patches of the Libac Jity (Schelhatimora wadrata), an attractive little plant with some flowers at midsuminer. It is reputed rave. A trailing Lobelia (I), purcurascens) has the upward aspect of the fower nearly white, but tinted behind and often coloured of the back of the leaves. The Fanfower (Scatzola vanosissima) is common, though rather thinty scatlered, as well as Dampierd stritta, a stmaller blue flower,
and more upright want of the same fanuly. Anisopogen is a father formidable Spear-Grass with its thire awns and considerable peretrating power. Ir is a fine example for the study of the grass spikelet as it does everylning on sucti a large scalc. Another unusual plant is the Cirlywig (Coscsis flexutosth), a sedge with very twisted growth and leaf slueaths at iutervals pn its stems, which give it the aspect of a plant of the Restio family. Another Caustis (C. petitandta) ocetrs at moist places, but this is a more widely-known plant. The Wooily Xanthosia (X. pilosa), also Enund, has its flowers tev together and is somewhat woody, bo that it is not at onve seen to belong to the Carrot family.

Near the main road there are sone wet flats, the road naturally avoiding the more defined gutlies. It is hot always easy to say which plants belong to the wet ground, as with summer rain the forest as a whole is moister than in many other districts, Restio complanalirs was found in these flats and several others of its family. Lycopodiwn densum, a rather robust form of clab moss, is plentsfui at places, The Flax-leat Heitly Myrtle (Bachea lenifolya) seams definitely to belong to these flats. It is a shrub with slender branches and had a few flowers in Jandary, apparently begimiug. It is recorded also in a somewhat different form in a noist situation neat Mt. Imlay across the border. The Mistletoe (Lordothius vitelintus) accurs in the forest, nearly always high up, but its fallen flowers reveal it. The flowers are large and bright coloured and the plant offen quite attractive. Near the coast, but not in the actual coastal scruth, the yellowish patches of the Golden Mistletoe are seen. All we observed were associated with other Mistletoes
 examples were obtained of the Golden Mistletoe parasitic on each of these.

South-weat of the township, near the coast, there is a large area of dwarf scrub with patches, of stunted trees, which may conventiently be called moorland, The present edge of the forest is abrupt and the trices somewhat stunted, which may indicate some elearing, but the moorland presents a type oi vegetation of its othn, it conditions due to exposure to wind and peethaps wind-cariued salt. Few flowers or fruits were seen on the trees and the foliage is not always quite normal, Some tree patcher about 10 or 12 feet higla were Angophoras with very little cloulst. One patch at Jeast aboin 8 ft . high with a few buds is ljest as a stunted form of Eucalyphas ciugunioides (E. Mhelleriono seense Jess pikely). The deaves were thick. It docs not seenl necessary to call it a variety; it may be only a result of the environment.

The low moortand vegctation consists Jargely of Castarinas$C$ distyda and C. patedraso. The Dagger Hakea necurs in low dense bushes crowded with flowers in January. In the forest it is talier and not dense. Bredotituyord tricuram is here of smaller growth than usual and the flowers deep coloured. In fact deep colours ate
common in this area, as in Common Heath, sone of which was in flower, and in Orithocoras sfrichane, the Homed Orchid. In this moor also is the Flag. Patersomia sericeo, deep purple, but its colour is, 1 think, usually deeper than the Patersonias near Melbourne. Other plants here include the Large Tongue Orchid and a Thysanotus, the Fanfower already mentioned, the Prickly Guinea Flower (Hibheftic nocularis), the Daphise Heath (Brachylomat (adinnoides) and a mall Boronia.

One of the most remarkable plants is the lobed Spyridium ( $S$. soppoflacount.), a miniature among the Rhamnaceae sometimes only a few inches high. Its small size at this locality is noticed by the Baront, as I'take it thet this is his locality given as "mouth of the Genoi River." A variety of Seneilo atestralis with toothed leaves (var Macrodonta) occurs with the tree patchcs. One of the eastern Geebungs, Persoomia lancsolota, occurs as scattered loushes in the moorland, jerhaps more as the land curves ower toward a creek. Near the headland coast reatree and Mclatenco arusillaris give some shelter.

The lowet palts of anany of the valleys have a vegetation of especiat interest, meluding several kinds of trees and various climbing plants, some of which are of large size. Lillypillies (Ekgestia Smihait) are prominent with Bolwarta (Eapomatia laurima). The Eupomatia often shows slender upright growth which curves over and sometumes cren Jooks like a talf climber. The young foliage is large and bright and aromatic; Anver buds wece present in January on low growth, but we did not see any of the flowers which are said to he strongly scented. The targe Pittosportum also oceurs, and the Notelaea and Elaencarpus already mentioned. The Notelaea varies in its leaf shape and size and the fruit colonr changes with the degree of maturity, but all examined seemed reterable to $N$. lomgifotio.

The largest of the climbers is a true grape-vine, Vitic hypoghasica. Its thick srems form gueat loops from tree to tree. Some former support has gore, leaning lengths of the climber in mid-air. The Stalked Doubah, Marsdond rasivata, is aiso commen, with the peculiar Howers and nuiky juice usual in the Asclepad family. Another woody climber is the Morimala (M. jasmmoides). It was of smaller growth, hat we found an-opportunity to obtain flowers where a fallen tree bad brought down the dimber with it. The Tecoma is rather more widespread, not confined to this kind of valley. Smilaza australis is a clintber of the lily family, of a peculiar secrion, with net veining in the leaf. It climht hy tendrils and is amed with substanpial prickles, so that it is a well-known impediment to travel. The Wombat-beery (Eustrophtu; Latioliva) beiongs to a quite difterent section of the Lily family. It is an asparagoid climber, somewhat resembling in aspect the broad-leaf Asparagus (or $M$ yesiphythwm) of gardens, which is often called Sinpilax in error. True Strilax is quite different.

The Rasp fern (Doodia aspora), with tinted frouds, is sometimes abwodan, and it a gully in the stceper comentry at the Narrows we foatd the Criceping Polypody (Cycioptornes satperns). In this gully also the Grass Flag, Libertia panictution, was found. Nearby a steep billside descends to the Narrows. Here we found the Flax Lily (Diandla toerulea). confirming the ocentrence of this spectes it Victouna. Here also wore the Prickly Shagay Pea (Oxybbinotmilobatum) and the Twining Guinea Flower (Hiuburtio dentala). At the ibot of the slope Dodonala triquetra ocens, as well as the commen D. quscosa, The Mattonwood, Rahanea (or Myrine) Howitiarma occurs thear the Lillypillies, but is not so linited. It extents westward also as jat as the valleys of the Keilot Plains. Some exauples showed an abundance of the purple fruits olothing flie stems just below the foliage. This habri of floweriug oun old stems behind the present growth is said to be frequent in some dense warm forests clsewbere. Upstream the Lillypilly valleys mergo into orilinary forest valleys, with such familiar trees as the Hazel Pomaderris and Blanketleaf (Bodfardia sal̈ctivo).

The coastal humnocks did not present any unustial features at the part visiled except a large form of the Sword Sedge (Lapidorperma gladiaturbs). The stindstit between the entrance and the clitis carried little but Cakile, but this is rew grounch. At the few places visited on the outer coast I did not frid any examples of the Scented Fanflower (Scoesola entendataceo), nor of Senerio spormbotas, nol Stachowasia spashulata, though these occur at Lakes Entrance. They might be formd an further search On the clif west of the entrance there are good platis of Alytim and sone Correa albo.

Among the rarer plants found at various jlaces were the Black Bogrush (Sthocus miolonostachyus), a Pulmenaea, apparently a nou-prickly form of $P$. styphelioides. The Molneca Birantle, whith ranges from Orbost to the Plilippines, was seen; it has a tather attractive red flower. Five species of Persoonia were observed. Other interesting species, though scarcely rate, molude the Tick Pea (Destrodtata varions), seen at various places. Several sjecies of $\mathrm{Halich} \boldsymbol{r y s u m}$ were found, including $H$. oblongifolians and ff . Borfori. The Showy Cassinia was also seen. A few late fowers of Teroikecs were collected and seem to inchade both $T$, pilosa and T. glandulosia. No doubr many plants not in flower escaped notice. Garrea rubra occurs in a form with a slightly pink tinge in the red flowers, differing in flower and leaf from the red Correa ar Fernbank, neir Bairnsdale, and more resembling a tall form figund near Kalimua, Scutslavia snollis, had been found in previdus years, and exhibited. A Mitrasocme, probably M. polyniesphta, was observed at thore than one place. Drosere spathulato was seen in a roadside drata it black moist soil. Goodenia baplyata, recorded for Genoa, occurs on the road some distance west of that township.

The Herbariunt staff has kindly compared several of the less familiar plants, for which we tender our best thanks.
